The jump problem for holomorphic functions on non-rectifiable arc and $\overline{\partial}$–equation

B. Kats

The jump problem is the following well known boundary value problem for analytical function. Let $\Gamma$ be a given arc on the complex plane $\mathbb{C}$. It is required to find analytical in $\mathbb{C}\setminus \Gamma$ function $\Phi(z)$ such that

$$\Phi^+(t) - \Phi^-(t) = f(t), \quad t \in \Gamma,$$

where $\Phi^+(t)$ and $\Phi^-(t)$ are limit values of $\Phi(z)$ at point $t \in \Gamma$ from the left and from the right correspondingly, and $f(t), t \in \Gamma,$ is given function. If arc $\Gamma$ is piecewise–smooth, then a solution of this problem is given by the Cauchy integral

$$\Phi(z) = \frac{1}{2\pi i} \int_\Gamma \frac{f(t)dt}{t-z}.$$  

It is convolution of distributions $E(z) \equiv (\pi iz)^{-1}$ and $\int_\Gamma f(t) \cdot dt$, where

$$\left\langle \int_\Gamma f(t) \cdot dt, \phi \right\rangle \equiv \int_\Gamma f(t)\phi(t)dt, \phi \in C^\infty_0(\mathbb{C}).$$

As $E$ is fundamental solution of differential operator $\overline{\partial} \equiv \frac{1}{2} \left( \frac{\partial}{\partial x} + i \frac{\partial}{\partial y} \right)$, since the differential equation

$$\overline{\partial} \Phi = \int_\Gamma f(t) \cdot dt$$

is distributional version of the jump problem.

If the arc $\Gamma$ is not rectifiable, then both the Cauchy integral and the distribution $\int_\Gamma f(t) \cdot dt$ lose their certainty. In the present work we construct generalization of $\int_\Gamma f(t) \cdot dt$ for non-rectifiable arcs such that solution of the equation (2) with this generalization in the right side is also solution of the problem (1) on non-rectifiable arc.
